DS-6030 Homework Module 7

Tom Lever

07/08/2023

DS 6030 | Spring 2023 | University of Virginia

8. In the lab, a classification tree was applied to the Carseats data set after converting Sales into a qualitative response variable.

Now we will seek to predict Sales using regression trees and related approaches, treating the response as a quantitative variable.

(a) Split the data set into a training set and a test set.

```

```
vector_of_predicted_sales <- predict(full_tree, newdata = testing_data)
vector_of_actual_sales <- testing_data$Sales
calculate_mean_squared_error(vector_of_predicted_sales, vector_of_actual_sales)</pre>
```

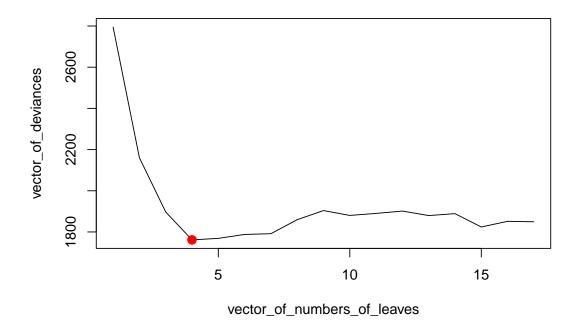

[1] 4.896065

When shelf location is good and price is less than 109.5 monetary units, our tree predicts that 12.190 thousand child car seats will be sold at each location in each time period.

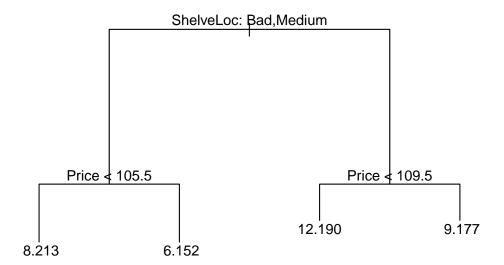

The test Mean Squared Error of our tree when predicting sales is 4.896 thousand².

(c) Use cross-validation in order to determine the optimal level of tree complexity. Does pruning the tree improve the test MSE?

```
object_of_types_prune_and_tree_sequence <- cv.tree(full_tree)
vector_of_numbers_of_leaves <- object_of_types_prune_and_tree_sequence$size
vector_of_deviances <- object_of_types_prune_and_tree_sequence$dev
plot(vector_of_numbers_of_leaves, vector_of_deviances, type = "l")
index_of_minimum_deviance <- which.min(vector_of_deviances)
optimal_number_of_leaves <-
    vector_of_numbers_of_leaves[index_of_minimum_deviance]
minimum_deviance <- min(vector_of_deviances)
points(
   optimal_number_of_leaves,
   minimum_deviance,
   col = "red",
   cex = 2,
   pch = 20
)</pre>
```

```
pruned_tree <- prune.tree(full_tree, best = optimal_number_of_leaves)
plot(pruned_tree)
text(pruned_tree, pretty = 0)</pre>
```

```
vector_of_predicted_sales <- predict(pruned_tree, newdata = testing_data)
calculate_mean_squared_error(vector_of_predicted_sales, vector_of_actual_sales)</pre>
```

[1] 6.785063

The test Mean Squared Error for the pruned tree is greater and less desirable than the Mean Squared Error for the full tree.

(d) Use the bagging approach in order to analyze this data. What test MSE do you obtain? Use the importance() function to determine which variables are most important.

Per An Introduction to Statistical Learning (Second Edition), bagging "is simply a special case of a random forest with [the number of variables randomly sampled as candidates at each split] m = p the number of predictors."

library(randomForest)

- # randomForest 4.7-1.1
- # Type rfNews() to see new features/changes/bug fixes.

```
index_of_column_Sales <-
    get_index_of_column_of_data_frame(training_data, "Sales")
data_frame_of_predictors <- training_data[, -index_of_column_Sales]
data_frame_of_sales <- training_data[, index_of_column_Sales]
number_of_predictors <- ncol(data_frame_of_predictors)
get_test_MSE_and_vector_of_ordered_percents_increase_in_MSE_for_random_forest <-
    function(mtry) {
    the_randomForest <- randomForest(
        formula = Sales ~ .,
        data = training_data,</pre>
```

```
mtry = mtry,
        importance = TRUE
    )
    vector_of_predicted_sales <-</pre>
        predict(the_randomForest, newdata = testing_data)
    test_MSE <- calculate_mean_squared_error(</pre>
        vector_of_predicted_sales,
        vector_of_actual_sales
    )
    matrix of importance metrics <- importance(the randomForest)</pre>
    vector_of_percents_increase_in_MSE <-</pre>

                             -1.691179
                                          -2.211183
```

The test Mean Squared Error for our bootstrap aggregation (BAg) is 2.974, which is 0.607 of the MSE for our full tree and 0.438 of the MSE for our pruned tree.

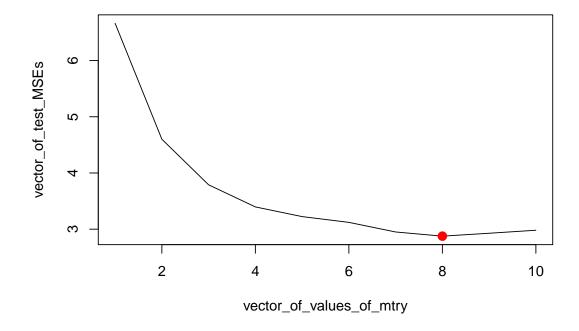

According to In a random forest, is larger %IncMSE better or worse?, "%IncMSE is the most robust and informative measure. IT is the increase in mse of predictions(estimated with out-of-bag-CV) as a result of variable j being permuted(values randomly shuffled)... the higher the number, the more important."

%IncMSE is highest for ShelveLoc followed by Price; ShelveLoc and Price are the two most important variables.

(e) Use random forests to analyze this data. What test MSE do you obtain? Use the importance() function to determine which variables are most important. Describe the effect of m, the number of variables considered at each split, on the error rate obtained.

```
data_frame_of_values_of_mtry_and_test_MSEs <- data.frame(</pre>
    matrix(NA, nrow = number of predictors, ncol = 2)
)
colnames(data_frame_of_values_of_mtry_and_test_MSEs) <- c("mtry", "test_MSE")</pre>
for (mtry in 1:number_of_predictors) {
    print(paste("mtry: ", mtry, sep = ""))
    data_frame_of_values_of_mtry_and_test_MSEs[mtry, "mtry"] <- mtry</pre>
    test_MSE_and_vector_of_ordered_percents_increase_in_MSE <-</pre>
        get_test_MSE_and_vector_of_ordered_percents_increase_in_MSE_for_random_forest(
            mtry = mtry
        )
    test_MSE <- test_MSE_and_vector_of_ordered_percents_increase_in_MSE$test_MSE</pre>
    vector_of_ordered_percents_increase_in_MSE <-</pre>
        test_MSE_and_vector_of_ordered_percents_increase_in_MSE$
            vector_of_ordered_percents_increase_in_MSE
    print(vector_of_ordered_percents_increase_in_MSE)
    data_frame_of_values_of_mtry_and_test_MSEs[mtry, "test_MSE"] <- test_MSE</pre>
}

See above plot for test Mean Squared Errors for different values of the number of variables randomly sampled as candidates at each split m. Test MSE decreases parabolically with number of variables to a minimum for m=8. In all cases ShelveLoc and Price are the most important predictors.

- (f) Now analyze the data using BART, and report your results. (skip this exercise)
- 9. This problem involves the OJ data set which is part of the ISLR package.
 - (a) Create a training set containing a random sample of 800 observations, and a test set containing the remaining observations.

(b) Fit a tree to the training data, with Purchase as the response and the other variables as predictors. Use the summary() function to produce summary statistics about the tree, and describe the results obtained. What is the training error rate? How many terminal nodes does the tree have?

```
full_tree <- tree(Purchase ~ ., data = OJ)
summary(full_tree)
#</pre>
```

```
# Classification tree:
# tree(formula = Purchase ~ ., data = OJ)
# Variables actually used in tree construction:
# [1] "LoyalCH" "PriceDiff" "ListPriceDiff"
```

```
# Number of terminal nodes: 8
```

- # Residual mean deviance: 0.7571 = 804 / 1062
- # Misclassification error rate: 0.1636 = 175 / 1070

Our full tree is a classification tree that predicts whether a customer will purchase Citrus Hill or Minute Maid orange juice. A tree is grown by binary recursive partitioning using the response in the specified formula, Purchase, and choosing splits from the terms of the right-hand-side, which in our case are all terms besides Purchase. The predictors actually used in tree construction are LoyalCH, PriceDiff, and ListPriceDiff. Purchase is a factor with levels CH and MM indicating whether the customer purchased Citrus Hill or Minute Maid Orange Juice. LoyaltyCH seems to be a rate of customer brand loyalty for CH between 0 and 1. PriceDiff seems to be net sale price of Minute Maid orange juice less net sale price of Citrus Hill orange juice in dollars. ListPriceDiff seems to be the list price of Minute Maid orange juice less list price of Citrus Hill orange juice in dollars. In our full tree there are 8 terminal nodes / leaves. The residual mean deviance for our full tree is 804/(1070-8). The training error rate / misclassification error rate for our full tree is 175/1070.

- (c) Type in the name of the tree object in order to get a detailed text output. Pick one of the terminal nodes, and interpret the information displayed.
- (d) Create a plot of the tree, and interpret the results.
- (e) Predict the response on the test data, and produce a confusion matrix comparing the test labels to the predicted test labels. What is the test error rate?
- (f) Apply the cv.tree() function to the training set in order to determine the optimal tree size.
- (g) Produce a plot with tree size on the x-axis and cross-validated classification error rate on the y-axis.
- (h) Which tree size corresponds to the lowest cross-validated classification error rate?
- (i) Produce a pruned tree corresponding to the optimal tree size obtained using cross-validation. If cross-validation does not lead to selection of a pruned tree, then create a pruned tree with five terminal nodes.
- (j) Compare the training error rates between the pruned and unpruned trees. Which is higher?
- (k) Compare the test error rates between the pruned and unpruned trees. Which is higher?
